ART-UNIT: 214

PRIMARY-EXAMINER: Poinvil; Frantzy

ATTY-AGENT-FIRM: Nixon Peabody LLP Kaufman; Marc S.

ABSTRACT:

A system for controlling the distribution and use of digital works using digital tickets. In the present invention, a "digital ticket" is used to entitle the ticket holder to exercise some usage right with respect to a digital work. Usage rights are used to define how a digital work may be used or distributed. Each usage right may specify a digital ticket which must be present before the right may be exercised. Digital works are stored in repositories which enforce a digital works usage rights. Each repository has a "generic ticket agent" which punches tickets. In some instances only the generic ticket agent is necessary. In other instances, punching by a "special ticket agent" residing on another repository may be needed.

9 Claims, 20 Drawing figures

Class vs. Instance

The last line of the main() method uses the System class from the java.lang package to display the current date and time. First, let's break down the line of code that invokes the println() method, then look at the details of the argument passed to it.

Class Methods and Variables

Let's take a look at the first segment of the statement:

```
System.out.println(today);
```

The construct--system out--is the full name for the out variable in the System class. Notice that the application never instantiated the System class and that out is referred to directly from the class name. This is because out is a class variable--a variable associated with the class rather than with an instance of the class. You can also associate methods with a class--class methods

To refer to class variables and methods, you join the class's name and the name of the class method or class variable together with a period ('.').

Instance Methods and Variables

Methods and variables that are not class methods or class variables are known as *instance methods* and *instance variables*. To refer to instance methods and variables, you must reference the methods and variables from an instance of the class

While System's out variable is a class variable, it refers to an instance of the PrintStream class (a member of the java.io package that implements the <u>The Standard Output Stream</u>.).

When the System class is loaded into the application, the class instantiates PrintStream and assigns the new PrintStream object to the out class variable. Now, you have an instance of a class so you can call one of its instance methods.

Class Date

S-month

- dey

- year

(neu Date ()

d. math

Systemout.println()

As you see, you refer to an object's instance methods and variables similar to the way you refer class methods and variables. You join an object reference (system.out) and the name of the instance method or instance variable (printlin()) together with a period ('.').

The Java compiler allows you to cascade these references to class and instance methods and variables together and resulting in constructs like the one that appears in the sample program:

System.out.println()

Sum it Up

Class variables and class methods are associated with a class and occur once per class. Instance methods and variables occur once per instance of a class.

- There are two kinds of methods in a class:
 - o Class methods messages to the class
 - o Instance methods messages to objects

class vs instance

Why do you really want to use an instance instead of a class.

Why do you really want to use an instance instead of a class?

The only conclusion I can come up with is time. If there are properties of a class that change over time and the class has at least one property that depends on another property from outside of it, then it makes sense to have an instance. An example is, say we have 50 plastic tubes that are all the same, but joined together in a tree like fashion. We could make each pipe an instance of a particular generic class or each pipe a different class that is a subclass of the generic class. If we are interested in modelling these pipes in a knowledgebase, then describing each as a different class makes sense. Each position at least gives some uniqueness to allow it to be a separate class. If we wish to use these pipes in a simulation, then we should create instances. This may be a tree of instances of the generic pipe that all the individual pipe classes derived from, or may be instances of the all the specialized pipes. That is not important. What is important is that the instances change over time, and may directly affect the values of properties in other instances.

My conclusion is that in ontologies, it only makes sense to represent objects as classes. Instances only make sense in time varying systems of objects.

A more relevant example. The branching of blood vessels. The initial solution to this was to create a single Vessel class that had 2 properties, ProximalToVessels and DistalToVessels, both of which have a range of 0 or more instances of Vessel.

It seems that this is a lazy solution for at least 2 reasons:

- 1. it requires us to name instances carefully as the name provides us the context, or useful information, about the particular instance.
- 2. we could replace the instances with any others and the knowledge base would still be semantically correct, where in fact it should be wrong.

١

Replacing the instances with Classes instead feels non-lazy because:

 We are now being definate about our label - it is now a type, and we tend to be careful with types.

we can now assert that relationships are semantically correct and feel confident that we can't go wrong, i.e. we can't replace a left aorta with a pulmonary artery.

The added bonus is that this is a simpler rule than mixing in instances in the knowledgebase. If for example we wanted to specialize the pulmonary artery and it was an instance, we need to then change this to a class definition, and should probably also update many of the properties that reference it to now point to this specialized class of Vessel. Making it a class to start off with means there is not hassle in deciding we want to specialize from it.

If we want to run a simulation, then making an instance of each node in the tree would make sense, as now the objects are individuals who's properties obtain values which vary over time.

I have added a document that addresses some of this. See **Readdressing Ontologies.**
